MDAR Reproducibility Checklist

Materials and Methods

Expression and purification of soluble recombinant H5N1 HA protein

The sequence for influenza A/Texas/37/2024 H5N1 HA was downloaded from Global Initiative on Sharing All Influenza Data (GISAID) (74). The ectodomain of HA sequence was subcloned into pFastbac-1 expression vector with N-terminal gp67 secreted signal peptide and a C-terminal trimerization domain followed by a thrombin site and 6x His-tag. The recombinant baculoviruses with HA gene were generated using a Bac-to-Bac baculovirus expression system in Sf9 cells (Thermo Fisher Scientific) as described previously (75). The recombinant soluble HA proteins were expressed in High Five cells (Thermo Fisher Scientific) with an MOI of 5-10 for each recombinant virus. After 72 hours, the soluble HA proteins were harvested from supernatant and then further clarified by centrifugation. The soluble HA proteins in clarified supernatant were purified by metal-affinity chromatography using Ni-nitrilotriacetic acid (Ni-NTA) resin (Qiagen) and buffer-exchanged into Tris-buffered saline (TBS, pH 8.0). The purified HA proteins were digested with trypsin in a final ratio of 1:1000 (wt/wt) and then further purified by size exclusion chromatography (SEC) using HiLoad 16/90 Superdex 200 column (GE Healthcare). Proteins produced in insect cells contain paucimannose N-glycans and lack more complex terminal glycans, such as sialylated N-glycans. In contrast, proteins expressed in mammalian cells are more complex, featuring different branching and terminal modifications. Glycans, especially those located near the receptor-binding site, can create steric hindrance for protein binding to their receptors. Whole virus expressed from eggs and MDCK cells exhibit similar binding patterns to HA expressed from insect cells (44), although one report shows that soluble HAs expressed with sialylated glycans in mammalian cells can exhibit different fine specificities to sialosides on a glycan microarray compared to HA expressed in insect cells, but these differences were abrogated when the HA glycans were desialylated as would naturally occur on the HA of virions due to the influenza neuraminidase (76). We would also expect here that the receptor binding specificity would be largely unaffected by expression of the Texas H5 HA in different platforms as there are no N-glycans proximal to the receptor binding site as there was in the mammalian study with H2 and H7 HAs (76). The purified HAs were used for the structure and binding studies.

Crystallization, data collection, and structure determination for HA and HA-receptor analogs complex.

The purified soluble HA proteins were concentrated to 10 mg/ml for crystallization trials. The initial crystallization condition for apo-HA (unliganded HA) was obtained from crystal screening on our automated Rigaku CrystalMation system at The Scripps Research Institute using JCSG Core Suite (QIAGEN) as precipitant. The crystallization screening was based on the sitting drop vapor diffusion method by mixing 0.1 μ l of protein with 0.1 μ l of the reservoir solution. To facilitate the crystallization of WT A/Texas/37/2024 H5N1 HA, we introduced a mutation (D240N) based on an H5 structure that we determined previously (77). This mutation is far from the receptor binding site. The optimized crystallization conditions were: 0.1 M Hepes, pH 6.7, 15% PEG6000 for apo-Texas HA; and 0.1M Hepes pH 6.9, 18% PEG6000 for Leu²²⁶-Texas HA. Crystals were harvested after one week and then soaked in a reservoir solution with 10% (v/v) ethylene glycol as cryoprotectant. For HA-receptor analogs complexes, we used LSTa (Neu5Ac α 2-3Gal β 1-3GlcNAc β 1-3Gal β 1-4Glc), and LSTc (Neu5Ac α 2-6Gal β 1-3GlcNAc β 1-3Gal β 1-4Glc). Apo-crystals were harvested and then soaked with ligands at a final concentration of 5 mM in the reservoir solution for 5-20 minutes. The crystals were then stored in liquid nitrogen until data collection. Diffraction data for Apo-HA and HA-ligand complexes were collected at

synchrotron radiation beamlines specified on the crystal data collection and statistics table S1. HKL2000 was used for data processing (78). Initial phases for apo-HA and HA-ligand complexes were solved by molecular replacement using Phaser with H5 HA (PDB: 5E30) as a model (79). Manual refinement was carried out in Coot and PHENIX (80, 81). For the LSTc complex, only one monomer of the HA trimer had interpretable density for all five sugar moieties of LSTc, whereas another HA monomer had well-resolved density for three to four monosaccharides, and the third monomer of the HA trimers does not have ligand built because of poor ligand density. Final refinement statistics for each crystal structure are summarized in table S1.

Preparation of biotinylated sialosides

A library of biotinylated sialosides composed of linear and N-linked glycans carrying one to three LacNAc repeats were synthesized essentially as previously described (82). As a final enzymatic step, linear and N-linked glycans were sialylated using either recombinant human ST6Gal-I to add sialic acid in an α 2-6 linkage, or rat ST3Gal-III to add sialic acid in an α 2-3 linkage. Biotinylation of the NH₂-terminated linker of the sialosides was achieved with NHS-LCLC-biotin (Thermo Scientific, cat no. 21343) and DIPEA (Sigma-Aldrich, cat no. 496219). All biotinylated glycans were confirmed by high-resolution mass spectrometry (HRMS) as follows: **3SLN₁-L**, ESI TOF-HRMS m/z calculated for C₄₉H₈₄N₇O₂₃S, [M + H]⁺: 1170.5334, found 1170.5379; **3SLN₂-L**, ESI TOF-HRMS m/z calculated for C₆₃H₁₀₈N₈O₃₃S, [M + 2H]²⁺: 768.3364, found 768.3373; **3SLN₃-L**, ESI TOF-HRMS m/z calculated for C₇₇H₁₃₁N₉O₄₃S, [M + 2H]²⁺: 950.9025, found 950.9019; **3SLN₁-N**, ESI TOF-HRMS m/z calculated for C₁₁₂H₁₈₁N₁₃O₆₉S, [M - 2H]²⁻: 1422.5409, found 1422.5355; **3SLN₂-N**, ESI TOF-HRMS m/z calculated for C₁₄₀H₂₂₆N₁₅O₈₉S, [M - 3H]³⁻: 1191.4463, found 1191.4417; **3SLN₃-N**, ESI TOF-HRMS m/z calculated for C₁₆₈H₂₇₃N₁₇O₁₀₉S, [M - 3H]³⁻: 1435.2037, found 1435.1959; **6SLN₁-L**, ESI TOF-HRMS m/z calculated for C₄₉H₈₄N₇O₂₃S, [M + H]⁺: 1170.5334, found 1170.5367; **6SLN₂-L**, ESI TOF-HRMS m/z calculated for C₆₃H₁₀₈N₈O₃₃S, [M + 2H]²⁺: 768.3364, found 768.3401; **6SLN₃-L**, ESI TOF-HRMS m/z calculated for C₇₇H₁₃₁N₉O₄₃S, [M + 2H]²⁺: 950.9025, found 950.9023; **6SLN₁-N**, ESI TOF-HRMS m/z calculated for C₁₁₀H₁₈₂N₁₂O₆₈S, [M + 2H]²⁺: 1396.0448, found 1396.0477; **6SLN₂-N**, ESI TOF-HRMS m/z calculated for C₁₃₈H₂₂₉N₁₄O₈₈S, [M + 3H]³⁺: 1174.4538, found 1174.4567; **6SLN₃-N**, ESI TOF-HRMS m/z calculated for C₁₆₆H₂₇₆N₁₆O₁₀₈S, [M + 3H]³⁺: 1418.2117, found 1418.2285.

ELISA

The recombinant purified HAs used in ELISA were concentrated to 3-5 mg/ml. Briefly, extended linear and biantennary α 2-3 and α 2-6 sialosides with biotin tag were incubated in streptavidin-coated high binding capacity 384-well plates (Pierce) in PBS, pH 7.4 at 4°C for 12 hours. Excess glycans were removed by washing with PBS containing 0.05% Tween-20 (PBST). The plates were then blocked with 1% bovine serum albumin (BSA) in PBS (BSA/PBS) buffer containing 0.6 μ M desthiobiotin for 2 hours. After 2 hours, the plates were washed with PBST three times before further assay. The HA proteins with His-tag were incubated with anti-His mouse IgG2a primary antibody (BioLegend, cat no. 362616) and HRP-conjugated goat anti-mouse IgG (H+L) secondary antibody (Invitrogen, cat no. G21040) in a 4:2:1 ratio (w/w/w) in BSA/PBS buffer and incubated on ice for 30 min. The HA-antibody complexes were then 3-fold serially diluted and transferred to glycan-coated plates and incubated at room temperature for 2 hours. The plates were then washed and 3,3',5,5' tetramethylbenzidine (TMB, Sigma-Aldrich, cat no. T0440) peroxidase substrate added to each well for 15 min at room temperature. The reaction was quenched by adding

2 M sulfuric acid and binding detected at 450 nm absorbance using a BioTek Synergy H1 microplate reader (Agilent). Each HA-glycan analysis in ELISA was performed in duplicate. *Maackia amurensis* agglutinin (MAA) and *Sambucus nigra* agglutinin (SNA) were used as experimental positive controls for binding to α 2-3 and α 2-6 sialosides, respectively.

Glycan array

Glycan microarray was generated and used in influenza HA receptor specificity evaluation as previously described (82, 83). The His-tagged HAs were incubated with anti-His mouse IgG2a primary antibody (BioLegend, cat no. 362616) and HRP-conjugated goat anti-mouse IgG (H + L) secondary antibody (Invitrogen, A001) in TBST in a 4:2:1 ratio on ice for 30 min. The HA-antibody mixtures were transferred to the microarray with six replicates of each glycan and incubated at room temperature for 60 min. After 60 min, the slides were washed with PBST twice, then water, and dried before scanning by an Innoscan 1100AL microarray scanner (Innopsys).

Surface plasmon resonance

SPR measurements were conducted on a Biacore S200 at room temperature. TBST (TBS with 0.005% Tween-20) buffer was used as running buffer and to reconstitute all protein and glycan molecules. The linear α 2-6 tri-LacNAc (6SLN₃-L, human receptor analogs) and α 2-3 tri-LacNAc (3SLN₃-L, avian receptor analogs) with biotin tag were immobilized on the chips (Cytiva SA S series chips). The immobilized level was targeted to 500 RU (response unit). A blank flow cell was treated in parallel without glycan injection. After immobilization, multicycle kinetic measurements were conducted on each recombinant hemagglutinin analyte. 5000 nM, 2500 nM, 1250 nM, 625 nM, 312.5 nM, 156.3 nM, 78.1 nM, 39.1 nM, 19.5 nM, 9.8 nM, 4.9 nM and 0 nM analyte were injected at 30 μ L/min for 120 s and followed by 240 s dissociation. After each cycle, 2 steps of 30 s regeneration with pH 2.7 glycine buffer were used to achieve a flat baseline signal. Final SPR sensorgrams were collected by reference channel subtraction and zero concentration subtraction. Static state affinity was calculated by Biacore evaluation software. The K_D values for WT-Texas HA against 3SLN₃-L and 6SLN₃-L were calculated by Biacore S200 evaluation software static affinity model.

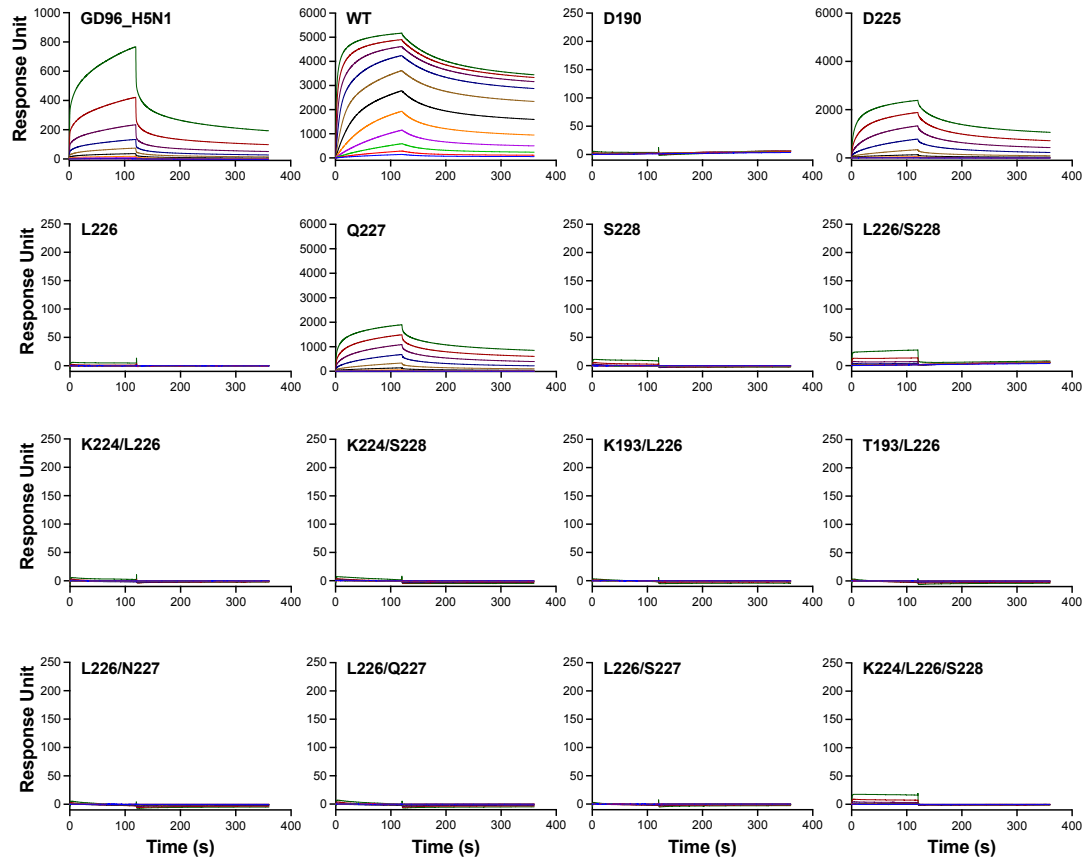

Fig. S1. Receptor binding of bovine Texas H5 HA mutants to α 2-3 sialylated glycans using SPR. Biacore diagrams representing the binding of each mutant to α 2-3 tri-LacNAc (3SLN₃-L). The y-axis shows the response. The response curves for different analyte concentrations are shown in different colors. Binding affinities were measured for wild-type and each HA mutant at 2-fold dilutions starting from 5 μ M. A/goose/Guangdong/1/1996 (GD96_H5N1) HA was used as an avian control for binding to α 2-3 sialosides. This figure is related to Figs. 1 and 2, figs. S2 and S3.

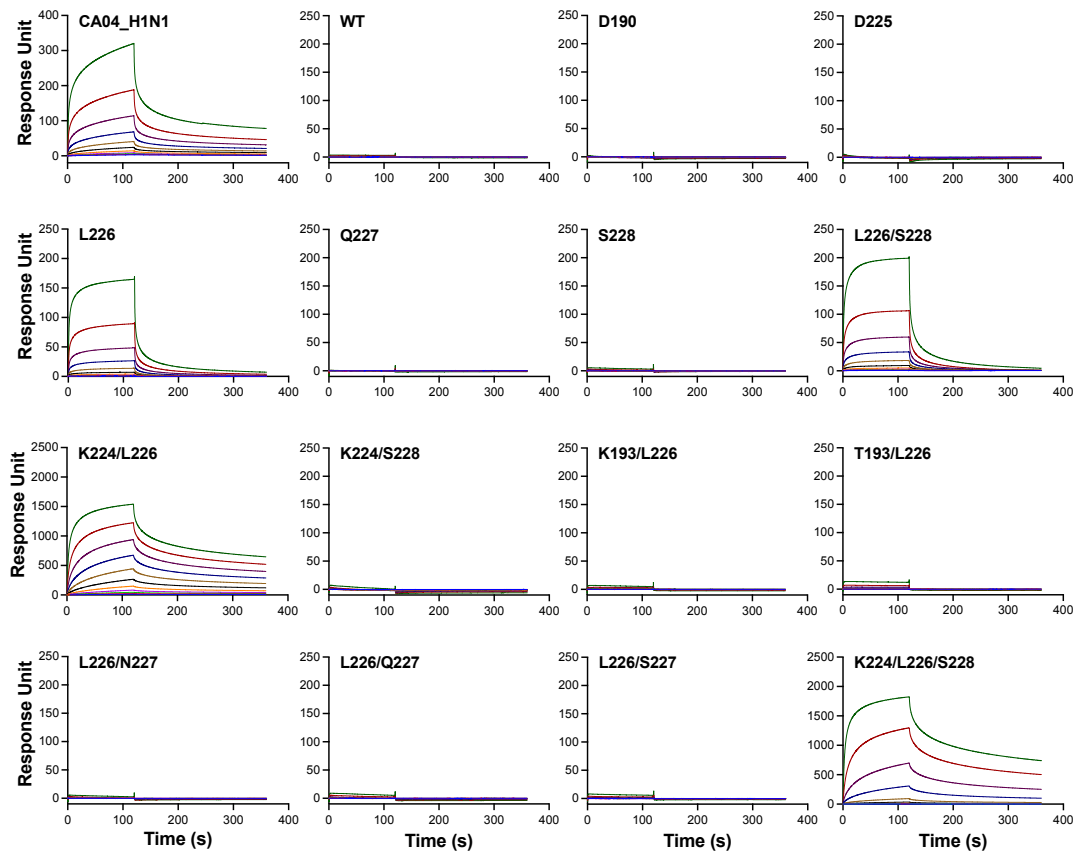

Fig. S2. Receptor binding of bovine Texas H5 HA mutants to α 2-6 sialylated glycans by SPR. Biacore diagrams of the binding of each mutant to α 2-6 tri-LacNAc (6SLN₃-L). The y-axis shows the response. The response curves for different analyte concentrations are represented in different colors. Binding affinities were measured for wild-type and each HA mutant at 2-fold dilutions starting from 5 μ M. A/California/04/09 (CA04) H1 HA was used as a positive control. This figure is related to Figs. 1 and 2, figs. S1 and S3.

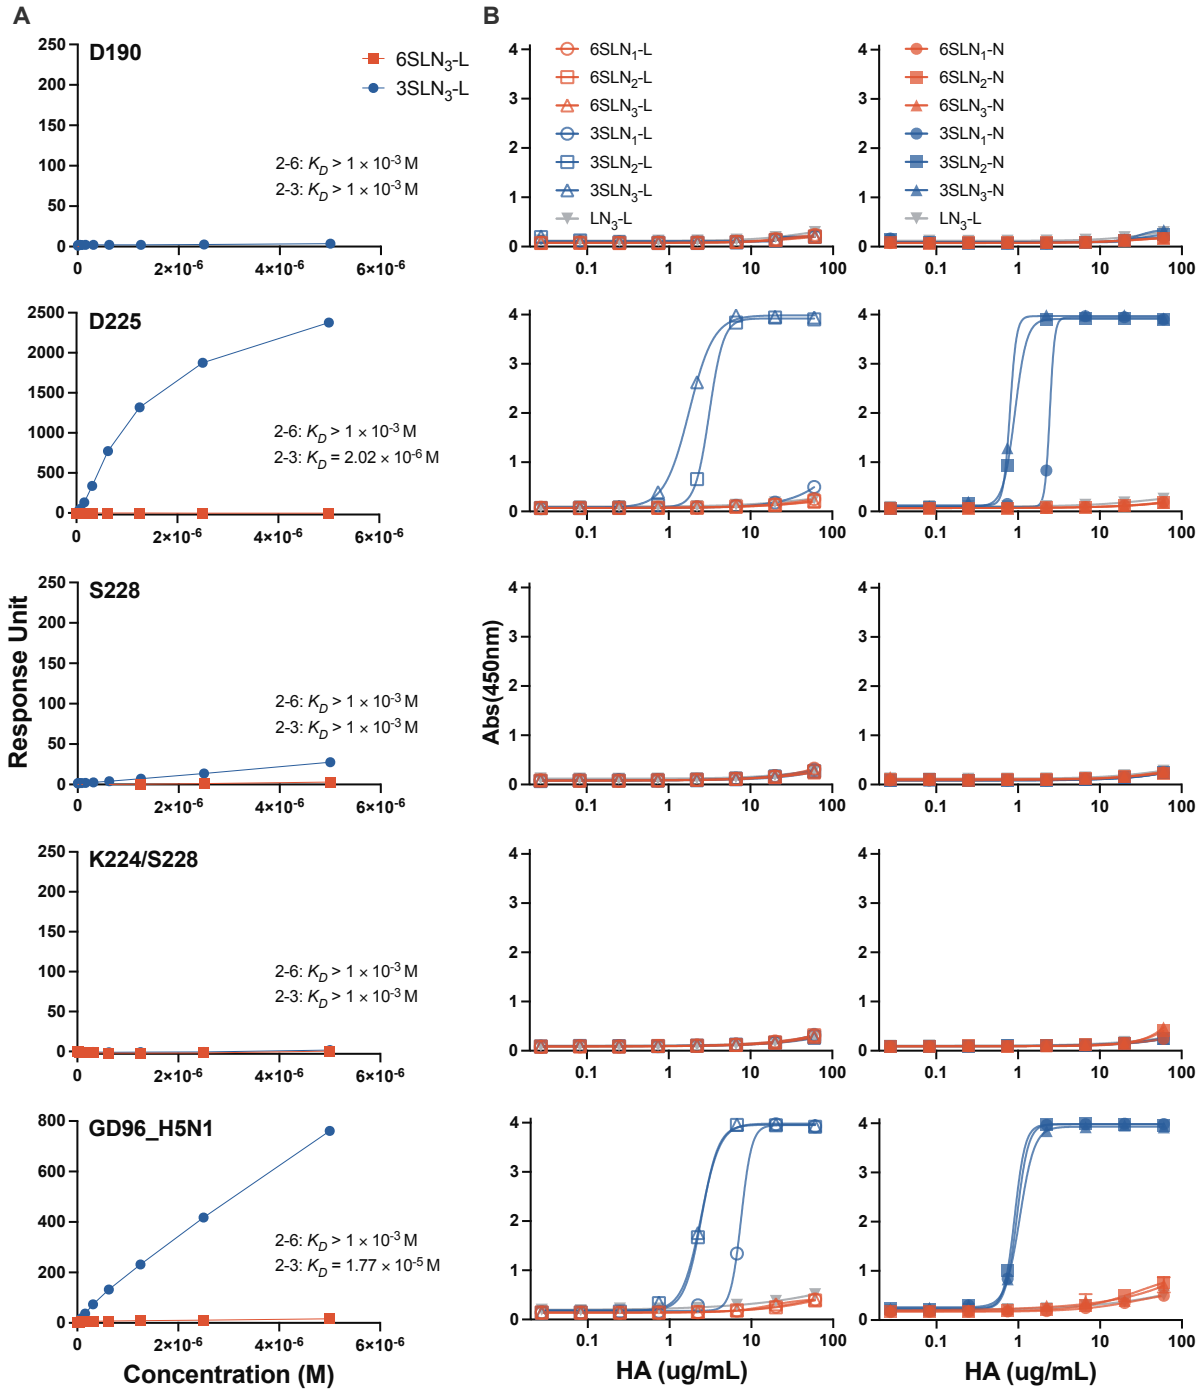

Fig. S3. Receptor binding specificity of bovine Texas H5 HA mutants by SPR and ELISA. Binding of Asp¹⁹⁰, Asp²²⁵, Ser²²⁸, and Lys²²⁴/Ser²²⁸ mutants to α 2-3 and α 2-6 sialosides were measured by SPR (A) and ELISA (B). The estimated K_D for each mutant was calculated by Biacore S200 evaluation software static affinity model. The response curves for the SPR assays are shown in figs. S1 and S2. The extended linear (left panel, open shapes) and biantennary (right panel, solid shapes) α 2-3 (blue) and α 2-6 sialosides (red) were used in the ELISA. Glycans for α 2-3 and α 2-6 sialosides are represented in Fig. 1. The H5 HA from A/goose/Guangdong/1/1996 (GD96_H5N1) was used as H5 avian control for binding to α 2-3 sialosides.

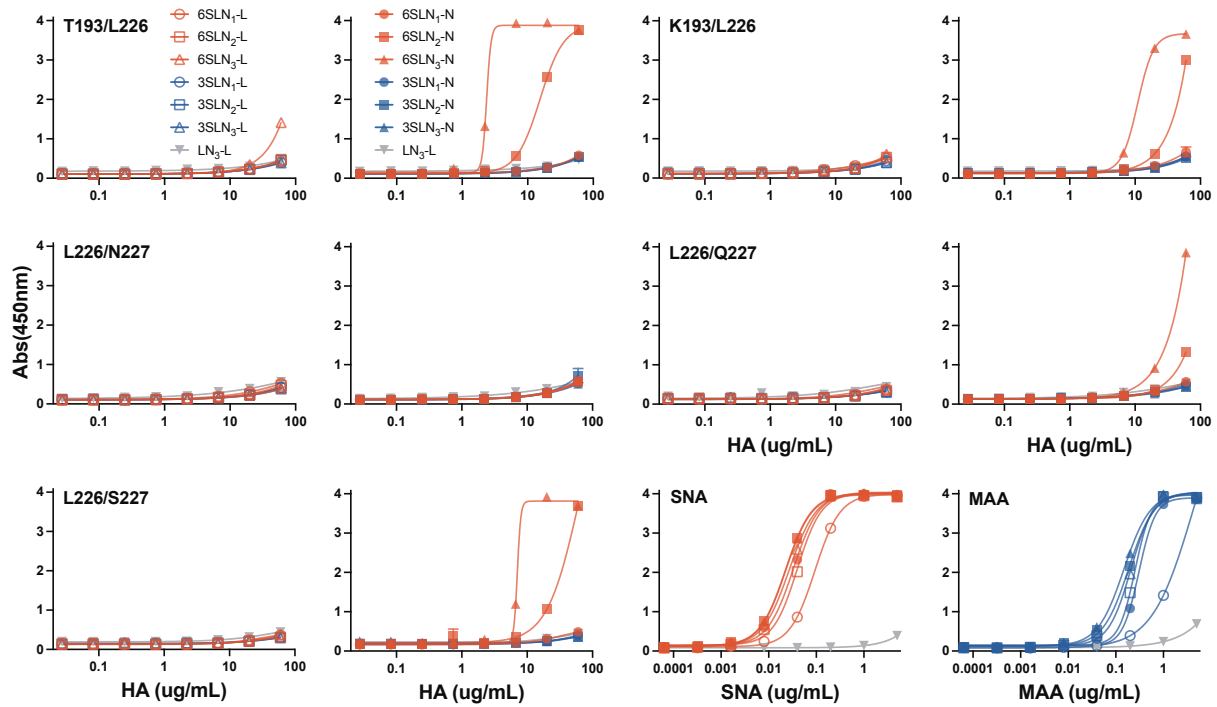

Fig. S4. Receptor binding specificity of bovine Texas H5 HA Leu²²⁶ mutant with other mutations measured by ELISA. Glycan binding of the Leu²²⁶ mutant with Thr¹⁹³, Lys¹⁹³, Asn²²⁷, Gln²²⁷, and Ser²²⁷ mutations was measured by ELISA with the extended linear (open shapes) and biantennary (solid shapes) α 2-3 (blue) and α 2-6 (red) sialosides. *Maackia amurensis* agglutinin (MAA) and *Sambucus nigra* agglutinin (SNA) were used as experimental controls for binding to α 2-3 and α 2-6 sialosides throughout the ELISA experiments in this study. LN₃-L with no sialic acid was used as a control.

Fig. S5. Electron density maps of avian and human receptors in the crystal structures of bovine Texas H5 HA-ligand complexes. 2Fo-Fc (**A**) and 2Fo-Fc unbiased omit (**B**) electron density maps for each ligand are contoured at a 1σ level and represented in black and brown mesh with the refined structures superimposed, respectively. LSTa (NeuAc α 2-3Gal β 1-3GlcNAc β 1-3Gal β 1-4Glc) from WT Texas HA - LSTa complex (left). LSTc (NeuAc α 2-6Gal β 1-4GlcNAc β 1-3Gal β 1-4Glc) from Texas HA Leu²²⁶ mutant - LSTc complex (right).

Fig. S6. Avian receptor analog LSTa contacts a symmetry-related HA in the crystal structure with bovine Texas H5 HA. The receptor binding site (RBS) of WT Texas H5 HA is depicted in a gold backbone cartoon. LSTa is shown with cyan carbons. An adjacent HA in a symmetry-related molecule is represented as a green backbone cartoon. Hydrogen bonds between LSTa Glc-5 and a symmetry-related HA are indicated in black dashes.

Fig. S7. Frequency of amino acids at HA residues in bovine influenza viruses. Weblogo plots were generated by using weblogo3. A total of 900 HA sequences collected and isolated from bovine influenza viruses from January 1, 2024 to October 1, 2024 in GISAID were analyzed and represented as HA1 and HA2. The red underline indicates residues that comprise the receptor binding subdomain. A triangle (▽) indicates mutations that are observed in fewer than 3 strains, while a star (☆) denotes mutations detected in more than 10 strains (for a total of 83 and 13 mutations observed at HA positions 132 and 160, respectively). The Ala to Thr mutation at residue 160 leads to a glycosylation site at Asn¹⁵⁸. H3 HA numbering is used. The mutations are so rare compared to the total sequences analyzed that no mutations show up on the logo plot.

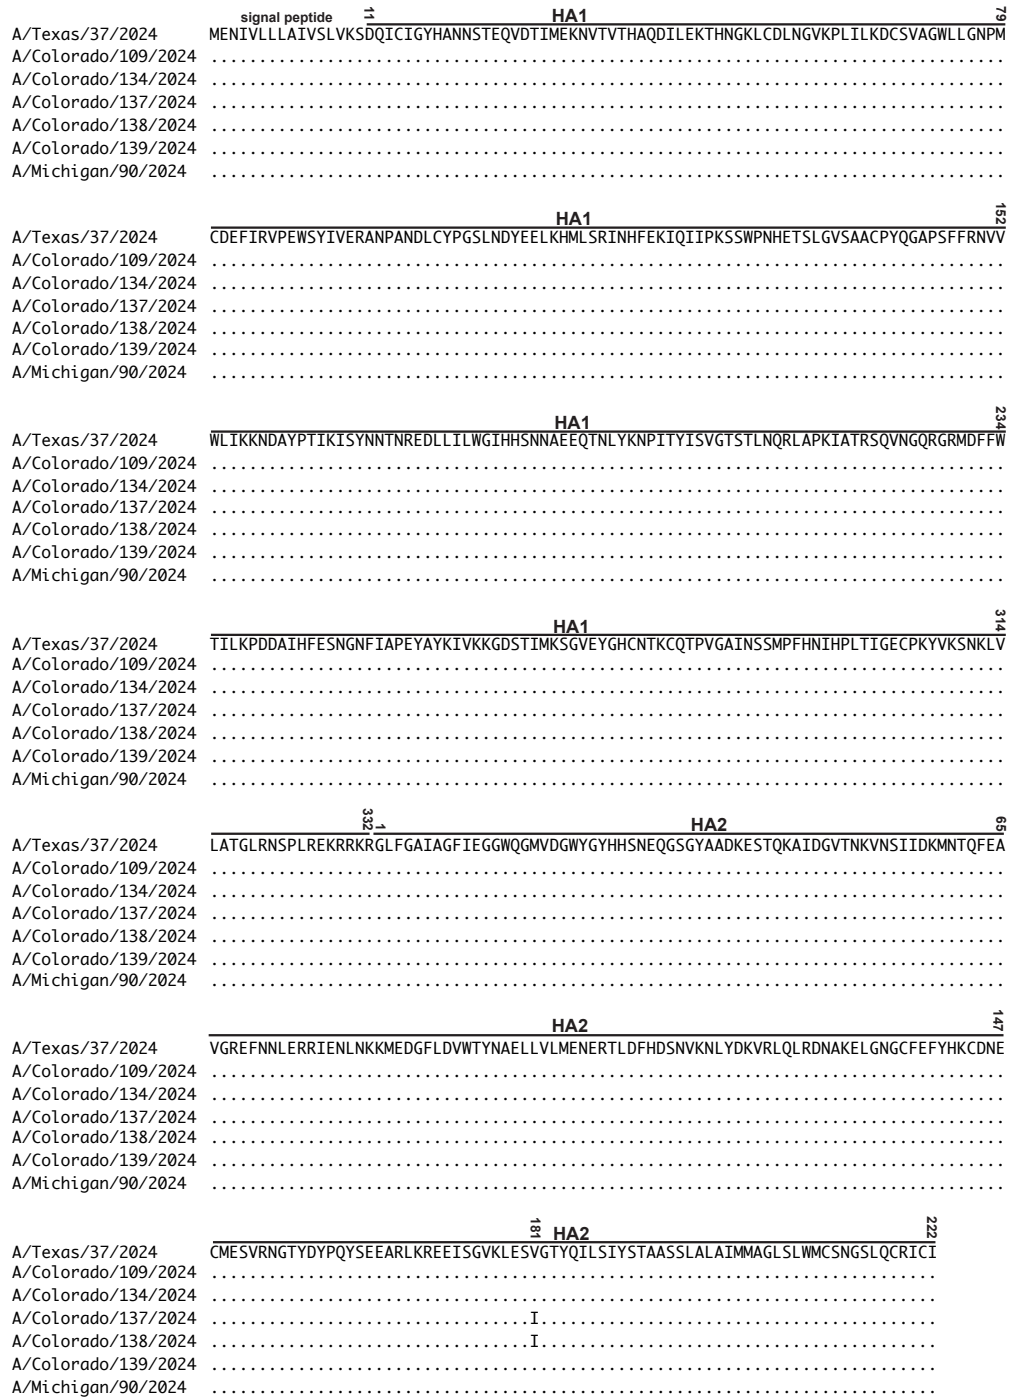

Fig. S8. Sequence alignment of HA from human infections with 2.3.4b H5N1 influenza viruses. A total 7 HA sequences from human infection with bovine and bird H5N1 influenza viruses deposited in GISAID this year were analyzed. Sequence variation after alignment with A/Texas/37/2024 is shown with a letter if a residue differs from A/Texas/37/2024 and with a dot (.) for conserved residues. H3 HA numbering is used.
